Report Manifest

Item	Description
Client	Puffer Finance
Target	pufETH Contracts

Version History

Version	Date	Description
1.0	Jan 29, 2024	First Release

About BlockSec BlockSec focuses on the security of the blockchain ecosystem and collaborates with leading DeFi projects to secure their products. BlockSec is founded by top-notch security researchers and experienced experts from both academia and industry. They have published multiple blockchain security papers in prestigious conferences, reported several zero-day attacks of DeFi applications, and successfully protected digital assets that are worth more than 5 million dollars by blocking multiple attacks. They can be reached at Email, Twitter and Medium.

Chapter 1 Introduction

1.1 About Target Contracts

Information	Description
Туре	Smart Contract
Language	Solidity
Approach	Semi-automatic and manual verification

The target of this audit is the code repository of pufETH Contracts¹ of Puffer Finance. The pufETH Contracts serve as a native liquid restaking token. Before the mainnet launch of Puffer, users could deposit stETH into the PufferVault and receive pufETH in return. Additionally, users can also utilize interfaces provided by PufferDepositor to swap tokens for stETH and deposit them into PufferVault. In the protocol, three different multisignature wallets control sensitive operations via the Timelock contract. These operations include modifying system configurations, suspending core contract functionality, depositing user-deposited stETH into EigenLayer, and initiating withdrawals from EigenLayer and Lido. Please note that the scope of this audit is limited to the following files:

- PufferDepositor.sol
- PufferVault.sol
- Timelock.sol
- DeployPuffETH.s.sol

The auditing process is iterative. Specifically, we would audit the commits that fix the discovered issues. If there are new issues, we will continue this process. The commit SHA values during the audit are shown in the following table. Our audit report is responsible for the code in the initial version (Version 1), as well as new code (in the following versions) to fix issues in the audit report.

Project	Version	Commit Hash	
ufETH Contracts	Version 1	4f1bbcd8d6210091baf5409c8b230a5961f0a2f7	
	Version 2	c46d4f1de6e22b2b8ff33111a7852225aef443e6	

1.2 Disclaimer

This audit report does not constitute investment advice or a personal recommendation. It does not consider, and should not be interpreted as considering or having any bearing on, the potential economics of a token, token sale or any other product, service or other asset. Any entity should not rely on this report in any way, including for the purpose of making any decisions to buy or sell any token, product, service or other asset.

This audit report is not an endorsement of any particular project or team, and the report does not guarantee the security of any particular project. This audit does not give any warranties on discovering all security issues of the smart contracts, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit cannot be considered comprehensive, we always

1

¹https://github.com/PufferFinance/pufETH

recommend proceeding with independent audits and a public bug bounty program to ensure the security of smart contracts.

The scope of this audit is limited to the code mentioned in Section 1.1. Unless explicitly specified, the security of the language itself (e.g., the solidity language), the underlying compiling toolchain and the computing infrastructure are out of the scope.

1.3 Procedure of Auditing

We perform the audit according to the following procedure.

- **Vulnerability Detection** We first scan smart contracts with automatic code analyzers, and then manually verify (reject or confirm) the issues reported by them.
- Semantic Analysis We study the business logic of smart contracts and conduct further investigation on the possible vulnerabilities using an automatic fuzzing tool (developed by our research team).
 We also manually analyze possible attack scenarios with independent auditors to cross-check the result.
- **Recommendation** We provide some useful advice to developers from the perspective of good programming practice, including gas optimization, code style, and etc.

We show the main concrete checkpoints in the following.

1.3.1 Software Security

- * Reentrancy
- * DoS
- * Access control
- * Data handling and data flow
- * Exception handling
- * Untrusted external call and control flow
- * Initialization consistency
- * Events operation
- * Error-prone randomness
- * Improper use of the proxy system

1.3.2 DeFi Security

- * Semantic consistency
- * Functionality consistency
- * Permission management
- * Business logic
- * Token operation
- * Emergency mechanism
- * Oracle security
- * Whitelist and blacklist
- * Economic impact
- * Batch transfer

1.3.3 NFT Security

- * Duplicated item
- * Verification of the token receiver
- * Off-chain metadata security

1.3.4 Additional Recommendation

- * Gas optimization
- * Code quality and style

Note The previous checkpoints are the main ones. We may use more checkpoints during the auditing process according to the functionality of the project.

1.4 Security Model

To evaluate the risk, we follow the standards or suggestions that are widely adopted by both industry and academy, including OWASP Risk Rating Methodology ² and Common Weakness Enumeration ³. The overall *severity* of the risk is determined by *likelihood* and *impact*. Specifically, likelihood is used to estimate how likely a particular vulnerability can be uncovered and exploited by an attacker, while impact is used to measure the consequences of a successful exploit.

In this report, both likelihood and impact are categorized into two ratings, i.e., *high* and *low* respectively, and their combinations are shown in Table 1.1.

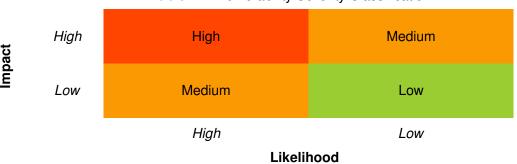

Table 1.1: Vulnerability Severity Classification

Accordingly, the severity measured in this report are classified into three categories: **High**, **Medium**, **Low**. For the sake of completeness, **Undetermined** is also used to cover circumstances when the risk cannot be well determined.

Furthermore, the status of a discovered item will fall into one of the following four categories:

- **Undetermined** No response yet.
- Acknowledged The item has been received by the client, but not confirmed yet.
- **Confirmed** The item has been recognized by the client, but not fixed yet.
- Fixed The item has been confirmed and fixed by the client.

³https://cwe.mitre.org/

Chapter 2 Findings

In total, we find **one** potential issue. Besides, we also have **four** recommendations and **four** notes.

- Low Risk: 1

- Recommendation: 4

- Note: 4

ID	Severity	Description	Category	Status
1	Low	Potential txHash conflicts in the Timelock contract's pending queue	Software Security	Fixed
2	-	Remove duplicated code	Recommendation	Fixed
3	-	Revise the compiler version	Recommendation	Fixed
4	-	Add a sanity check on newPauser	Recommendation	Fixed
5	-	Revise the inconsistent access controls on deposit logic	Recommendation	Fixed
6	-	Potential risks of MEV attacks	Note	-
7	-	Ensure the standard implementation of accessManager	Note	-
8	-	Necessity to implement a fair EigenLayer airdrop distribution mechansim	Note	-
9	-	Ensure no stETH tokens remain in the PufferDepositor contract	Note	-

The details are provided in the following sections.

2.1 Software Security

2.1.1 Potential txHash conflicts in the Timelock contract's pending queue

Severity Low

Status Fixed in Version 2

Introduced by Version 1

Description In the Timelock contract, the queueTransaction function keeps track of pending operations using the queue mapping, with the txHash serving as the key. This txHash is the keccak256 hash resulting from the encoding of target and callData, as shown on line 123. Operations are eligible for execution only after the lockedUntil time has passed. However, there is a risk that a new operation with the same target and callData could overwrite an existing one in the queue.

```
function queueTransaction(address target, bytes memory callData) public returns (bytes32) {
   if (msg.sender != OPERATIONS_MULTISIG) {
      revert Unauthorized();
   }
   }
   bytes32 txHash = keccak256(abi.encode(target, callData));
   uint256 lockedUntil = block.timestamp + delay;
   queue[txHash] = lockedUntil;
}
```

```
127     emit TransactionQueued(txHash, target, callData, lockedUntil);
128
129     return txHash;
130  }
```

Listing 2.1: Timelock.sol

Impact The previous conflicting operation cannot be executed due to the overwriting.

Suggestion Add a unique operation_id for each operation.

2.2 Additional Recommendation

2.2.1 Remove duplicated code

```
Status Fixed in Version 2
Introduced by Version 1
```

Description In the initiateStETHWithdrawalFromEigenLayer function of the PufferVault contract, the assignment on line 171 is duplicated and can be removed.

```
170 uint256[] memory strategyIndexes = new uint256[](1);
171 strategyIndexes[0] = 0;
```

Listing 2.2: PufferVault.sol

Impact N/A

Suggestion Remove the duplicated code.

2.2.2 Revise the compiler version

Status Fixed in Version 2
Introduced by Version 1

Description To enable naming the mapping parameters, the Timelock contract should specify that the compiler version is equal to or greater than 0.8.18.

```
95 mapping(bytes32 transactionHash => uint256 lockedUntil) public queue;
```

Listing 2.3: Timelock.sol

Impact N/A

Suggestion Revise the compiler version.

2.2.3 Add a sanity check on newPauser

Status Fixed in Version 2
Introduced by Version 1

Description The _setPauser function in the Timelock contract does not verify whether the newPauser is non-zero.

```
225  function setPauser(address newPauser) public {
226    if (msg.sender != address(this)) {
227       revert Unauthorized();
228    }
229    _setPauser(newPauser);
230  }
```

Listing 2.4: Timelock.sol

Impact N/A

Suggestion Add the corresponding sanity check.

2.2.4 Revise the inconsistent access controls on deposit logic

Status Fixed in Version 2

Introduced by Version 1

Description An inconsistency exists in the access controls between the PufferDepositor and PufferVault contracts regarding the deposit functionality.

Specifically, the PufferDepositor contract declares the depositing functions (swapAndDeposit1Inch, swapAndDepositWithPermit1Inch, swapAndDeposit, swapAndDepositWithPermit, and depositWstETH) with a restricted modifier for access control. However, this access control is not applied to the deposit and mint functions in the PufferVault contract. This means that, even when the PufferDepositor contract is paused, the deposit and mint functions can still be invoked without limitations. Consequently, users can still exchange tokens for stETH directly on a third-party DEX and deposit them into the PufferVault without any restrictions.

Impact N/A

Suggestion Apply consistent access control logic for depositing functions.

2.3 Note

2.3.1 Potential risks of MEV attacks

Description The swapAndDeposit1Inch function in the PufferDepositor contract allows users to specify swap parameters for swapping tokens for stETH via the _1INCH_ROUTER. However, the function does not verify whether slippage protection is set in the callData, potentially exposing users to sandwich attacks.

Feedback from the Project We acknowledge this as a risk and will have warnings on the frontend to set their slippage accordingly when interfacing with 1inch / sushi.

2.3.2 Ensure the standard implementation of accessManager

Description The accessManager contract code is not included in the provided repository or dependencies and is therefore outside the scope of this audit. Given that the accessManager manages critical access controls, it is assumed for the purposes of this audit that its implementation follows the standardized OpenZeppelin AccessManager. Furthermore, it is recommended that the accessManager be governed by a multisignature wallet to mitigate potential risks of centralization.

```
98  function initialize(address accessManager) external initializer {
99     __AccessManaged_init(accessManager);
100     __ERC20Permit_init("pufETH");
101     __ERC4626_init(_ST_ETH);
102     __ERC20_init("pufETH", "pufETH");
103 }
```

Listing 2.5: PufferDepositor.sol

Feedback from the Project We deploy OZ's AccessManager in the deployPufETH.s.sol, the ownership of AccessManager is transferred to TimeLock after deployment.

2.3.3 Necessity to implement a fair EigenLayer airdrop distribution mechansim

Description The PufferVault deposits stETH into EigenLayer on behalf of users to farm points for EigenLayer airdrops. However, in the current PufferVault contract implementation, there is no mechanism to distribute airdrops to depositors. The project should ensure that there is a fair mechanism for distributing airdrops from EigenLayer. If the distribution relies solely on user shares in the vault, it may introduce the potential for front-running arbitrage.

Feedback from the Project This would be done in mainnet implementation of the contract. Will likely transfer Eigen tokens to a distributor contract.

2.3.4 Ensure no stETH tokens remain in the PufferDepositor contract

Description The PufferDepositor contract allows users to swap any tokens on third-party DEXes (e.g., linch, SushiSwap) for stETH and deposits the acquired stETH into the PufferVault contract. However, any remaining stETH in the PufferDepositor contract could potentially be claimed by anyone. For instance, the swapAndDeposit1Inch function does not validate the swapData passed to linch. Exploiting this, users could manipulate the amountOut returned and claim extra stETH.

```
50
      function swapAndDeposit1Inch(address tokenIn, uint256 amountIn, bytes calldata callData)
51
         public
52
         virtual
53
         restricted
54
         returns (uint256 pufETHAmount)
55
      {
56
         SafeERC20.safeTransferFrom(IERC20(tokenIn), msg.sender, address(this), amountIn);
57
         SafeERC20.safeIncreaseAllowance(IERC20(tokenIn), address(_1INCH_ROUTER), amountIn);
58
59
         // PUFFER_VAULT.deposit will revert if we get no stETH from this contract
60
         (bool success, bytes memory returnData) = _1INCH_ROUTER.call(callData);
         if (!success) {
61
62
             revert SwapFailed(address(tokenIn), amountIn);
63
         }
64
65
         uint256 amountOut = abi.decode(returnData, (uint256));
66
67
         if (amountOut == 0) {
68
             revert SwapFailed(address(tokenIn), amountIn);
```

```
69  }
70
71  return PUFFER_VAULT.deposit(amountOut, msg.sender);
72 }
```

Listing 2.6: PufferDepositor.sol

According to the protocol design, the PufferDepositor contract is not intended to hold assets, rendering the aforementioned attack vector unfeasible. The only exception applies to scenarios involving accidental token transfers to this contract.

Feedback from the Project The PufferDepositor does not custody funds. We are relying on the 1inch backend to supply a correct route and then the stETH is deposited to the PufferVault.
